PyGame

- is a set of Python modules which sits on top of the excellent SDL library
- allows you to create fully featured games and multimedia programs in the python language
- PyGame is highly portable and runs on nearly every platform and operating system

PyGame

- it has the ability to initialise screen resolution or window size
- sprites, sound, collisions, keyboard, mouse, joystick events
- images, text can all be rendered to the 2D screen (or surface)
- fast image copies are achieved using the SDL (Simple DirectMedia Layer)

Is Python suitable for gaming?

- 30 frames per second is often quoted as the minimum necessary for smooth graphics
 - this means you must compute the next frame in under 1/30 of a second ≈ 30 milliseconds
- for 2D games PyGame is a very good solution
 - rapid prototyping
 - you can convert any slow pieces of Python into C if necessary and call these from Python
 - classically 90% of the time is spent in 10% of the code

Is Python suitable for gaming?

- abridged (http://www.pygame.org/docs/tut/intro/ intro.html)
- games are often split into two components
 - game engine
 - game logic
- most of the time the game engine must run really fast whereas the game logic requires less processing power
 - game engine written in C exploiting the SDL and presented as PyGame modules
 - game logic your python code

Game tools implemented in Python

there are many, for example: \(\text{https://www.blender.org} \)

Bouncing ball

```
#!/usr/bin/python3
import sys, pygame

width = 320
height= 240
speed = [2, 2]
black = (0, 0, 0)

pygame.init ()
screen = pygame.display.set_mode([width, height])
ball = pygame.image.load("ball.png").convert()
ballrect = ball.get_rect()
```

Bouncing ball

```
while True:
    for event in pygame.event.get ():
        if event.type == pygame.QUIT:
            sys.exit(0)

ballrect = ballrect.move (speed)
    if ballrect.left < 0 or ballrect.right > width:
        speed[0] = -speed[0]
    if ballrect.top < 0 or ballrect.bottom > height:
        speed[1] = -speed[1]

screen.fill(black)
    screen.blit(ball, ballrect)
    pygame.display.flip()
```

■ the ball can be taken from here: ball.png ⟨ball.png⟩

- Reference (http://www.pygame.org/docs/tut/intro/intro.html)
- import pygame imports the package with all the available PyGame modules pygame.init() initialises each of these modules
- pygame.display.set_mode() creates the graphic window

- PyGame represents images as Surface objects
 - display.set_mode() creates a new Surface object that represents the actual displayed graphics
 - any modification to this Surface becomes visible on the monitor
- pygame.image.load().convert() loads in the ball image
 - we convert it to a fast internal format

- the program is initialised and ready to run so we enter an infinite loop in which we check for user input, move the ball, and then draw the ball
- ballrect = ballrect.move(speed) updates the ball position
- the two if statements check to see whether the ball has touched the edge of the window
 - the then section bounces the ball back
- screen.fill(black) erases everything on the screen
- screen.blit (ball, ballrect) redraw the ball at the new position

pygame.display.flip() now make the screen visible

Detail

- notice that PyGame uses double buffering
 - we can update the screen piece at a time and the user sees nothing
 - only when we call pygame.display.flip() does the screen become visible
 - ensures speed and near instant updates
- it also allows us to use high level techniques such as screen.fill(black) without much of a performance penalty
